Foreword

The Great Barrier Reef is one of the truly majestic places on our planet. Its size and brilliance make it observable even from space. Few ocean areas are known as well globally as the 2,300 km of reefs that extend over the Australian east coast.

Comprised of more than 2,900 individual reefs that form its foundation, the Great Barrier Reef World Heritage Area encompasses a diversity of habitats, plants and animals of outstanding universal value. Scattered throughout its footprint are islands, mangroves and marine life of infinite variety. Like the Galapagos, the Great Barrier Reef has singular characteristics found nowhere else on Earth.

But, all of this is under threat as never before.

Global climate change is a virtual sword of Damocles hanging over the very heart of the Great Barrier Reef. History reveals that reefs have been faced with changes in the past, including fluctuations in water temperature, sea level and acidification. Climate change has accelerated this rate of change, coinciding with mounting pressure from human uses. These threats are certainly not unique to the Great Barrier Reef. Around the world, coral reefs are faced with impacts from poor water quality, overfishing, physical damage and climate change. Experts estimate that 20 percent of the world's coral reefs have been effectively destroyed and show no prospect of recovery, another 24 percent are under imminent risk of collapse through human pressures and 26 percent more are under longer-term threat. What makes the Great Barrier Reef unique is that, so far, it has remained in relatively good condition compared to other reefs around the world.

The timing of this book is critical. There is consensus amongst climate experts about the severity of climate change and its link to greenhouse gas emissions. We are now more certain about the amount of change that we can expect and its velocity. Take coral bleaching as an example. In 1998, we saw the world's first recorded global coral bleaching event. Many coral reefs were devastated by rises in sea temperature that exceeded the thresholds that can be tolerated by corals. Since then, worldwide coral reefs have continued to experience coral bleaching and the frequency and potentially irreversible impacts of these events is increasing.

Climate change poses an enormous danger and a new challenge for the protection of our natural heritage. What can marine managers do about changes that are worldwide in scope? We must start with understanding what the impacts on tropical marine ecosystems could be. Identifying the most sensitive species and habitats is an important outcome of this book. Identifying impacts that the ecosystem cannot tolerate is another. Efforts can then be targeted towards protecting these areas.

Unbiased experts are the key to finding solutions. This peer-reviewed book has been prepared by leading tropical marine and climate scientists. As we proceed down the inevitable path of climate change, the idea of change will and has become fundamental to understanding our environment and its role in shaping our ecosystems. Students today will emerge into a world of research and decision-making that did not exist for their predecessors. The authors of this book have provided the first text to assess the role of climate change on an ecosystem as large and diverse as the Great Barrier Reef.

As we experience climate change, we are starting to see real action to reduce greenhouse gas emissions. Governments and industries from around the world are accepting the reality of climate change and are building strategies to reduce their carbon footprint. These efforts must continue. We are committed to some change and we must prepare for it. But efforts to reduce greenhouse gas emissions and the extent of climate change is in our hands.

Based on solid facts, we must work together to find solutions. For without solutions, the Great Barrier Reef and all life is in peril.

Jean-Michel Cousteau
Founder and President, Ocean Futures Society

Contents

Preface..... IX
Acknowledgements..... X

Part I: Introduction

1. Introduction to the Great Barrier Reef and climate change..... 1
2. Climate and climate change on the Great Barrier Reef..... 15
3. Impacts of climate change on the physical oceanography of the Great Barrier Reef..... 51
4. Ecological resilience, climate change and the Great Barrier Reef 75

Part II: Species and species groups

5. Vulnerability of marine microbes on the Great Barrier Reef to climate change 97
6. Vulnerability of Great Barrier Reef plankton to climate change..... 121
7. Vulnerability of macroalgae of the Great Barrier Reef to climate change 153
8. Vulnerability of seagrasses in the Great Barrier Reef to climate change 193
9. Vulnerability of mangroves and tidal wetlands of the Great Barrier Reef
to climate change 237
10. Vulnerability of reef-building corals on the Great Barrier Reef to climate change 271
11. Vulnerability of benthic invertebrates of the Great Barrier Reef to climate change..... 309
12. Vulnerability of fishes of the Great Barrier Reef to climate change..... 357
13. Vulnerability of chondrichthyan fishes on the Great Barrier Reef to climate change..... 393
14. Vulnerability of seabirds on the Great Barrier Reef to climate change 427
15. Vulnerability of marine reptiles in the Great Barrier Reef to climate change..... 465
16. Vulnerability of marine mammals in the Great Barrier Reef to climate change..... 497

Part III: Habitats

17. Vulnerability of coral reefs of the Great Barrier Reef to climate change..... 515
18. Vulnerability of pelagic systems in the Great Barrier Reef to climate change 555
19. Vulnerability of coastal and estuarine habitats in the Great Barrier Reef
to climate change 593

20. Vulnerability of island flora and fauna in the Great Barrier Reef to climate change.....	621
21. Vulnerability of geomorphological features in the Great Barrier Reef to climate change	667
22. Using the past to understand the future: palaeoecology of coral reefs.....	717

Part IV: Enabling management

23. Climate change and the Great Barrier Reef: industries and communities.....	745
24. The Great Barrier Reef and climate change: vulnerability and management implications.....	773
Glossary	803
Symbol glossary	809

Preface

In many ways, the expert knowledge compiled in this book confirms what we already know: that the Great Barrier Reef is highly vulnerable to climate change. However, this unprecedented synthesis of current and emerging knowledge takes our understanding to a new level. In doing so, it increases our concern about the future but also gives us cause for optimism.

We now have a much deeper understanding about the extent and range of climate sensitivities that exist within the GBR ecosystem and, significantly, about the gaps in our knowledge. This heightened awareness increases our concern about the fate of corals – which build and maintain the foundations of the GBR – while also bringing into focus the vulnerabilities of many other components of the ecosystem. Although the size of the GBR and the effective long-term management regime afford it some protection from climate change compared to other tropical marine ecosystems, this assessment makes it clear that further degradation is unavoidable. However, there is much scope for minimising the negative impacts of climate change, and for avoiding the worst of their consequences.

The new opportunities for meaningful responses to climate change provide the basis for our optimism. This assessment identifies specific strategies for reducing the vulnerability of particularly sensitive species and habitats, while also refining our knowledge about ways to further restore and maintain the resilience of the ecosystem. While reductions in the rate and extent of climate change remain the single most important goal if we are to improve the prognosis for tropical marine ecosystems, actions to build the resilience of the GBR will be instrumental in averting what leading scientists have called the “coral reef crisis”. Effective management of the GBR has never been more important.

This assessment was commissioned by the Great Barrier Reef Marine Park Authority, in partnership with the Australian Greenhouse Office, to comprehensively assess current knowledge about climate change vulnerability, and to identify strategies for building resilience. These insights provide the foundations for the GBR Climate Change Action Plan, which will help GBRMPA and its partners navigate toward a healthy GBR that is more resilient to climate change. We hope that it will be of value to our international colleagues who share the responsibility of protecting tropical marine ecosystems for their beauty, their productivity, and for future generations.

Hon Virginia Chadwick
Chair, Great Barrier Reef Marine Park Authority

Acknowledgements

Production of this book has been made possible through financial support from the Australian Greenhouse Office and the Climate Change Program at the Great Barrier Reef Marine Park Authority. We are particularly indebted to Jo Mummery and John Higgins of the Australian Greenhouse Office for their guidance and support.

We are grateful to the vast array of climate and tropical marine experts from a diversity of institutes and disciplines who have so willingly contributed to this publication. We appreciate the effort required by authors in tackling such a daunting assessment and the time taken away from core research. We would also like to thank the vast number of nationally and internationally recognised experts who reviewed chapters and shared their thoughts and experiences with us in the compilation of this book.

Many others have played less obvious, but equally important roles. In particular, we wish to acknowledge Catherine Collier for her conceptual diagram expertise, image sourcing and enthusiastic assistance with compiling this publication, and Jeff Maynard and Michelle Heupel for their technical assistance and covering the extra group workload.

Development of this publication would not have been possible without the support of many groups and individuals. Within the Great Barrier Reef Marine Park Authority, senior management provided input to ensure this book was highly relevant to marine protected area management. We particularly acknowledge the leadership and support given by Virginia Chadwick, Andrew Skeat and David Wachenfeld. We are also grateful to Sara Trenerry, Brian Dare, Jo McIntosh, Katie Munkres, Suzie Davies and Julie Jones for their assistance with the production of this book.

Individual authors would also like to thank colleagues who provided thoughts and data in the compilation of their chapters. In particular, Severine Choukroun for the water column model; Mike Mahoney and Matthew Slivkoff for satellite image processing; David Bourne and Andrew Negri for helpful discussions and advice; Winston Ponder for review comments; Leone Lemmer at the Australian Museum for library assistance; Maya Srinivasan, Morgan Pratchett, David Booth, Mike Emslie, Tony Ayling, Gerry Allen and Rudie Kuitert for access to data; Terence Walker, Rory McAuley, John Stevens, Christine Dudgeon and Richard Pillans whose input and advice helped form the basis of the chondrythian assessment; Steven Stanley; Rosemary Gales; Mark Holdsworth; Chloe Schauble; Andrea Phillott; Kirstin Dobbs; Mark O'Callaghan for literature searches; John Neldner; Claire Speedie; Gillian Naylor and Heidi Schuttenberg.

Funding and travel support for some authors was also provided by the Microbial Observatories Program, US National Science Foundation (MCB-0238515), the Coral Reef Targeted Research Project, Australian Research Council Centre for Excellence in Reef Studies, CSIRO Cleveland, the Queensland Parks and Wildlife Service, Birds Australia, Australian Geographic, Birds Queensland and James Cook University.
